

Garden propagations
one becoming many
A leaf or stem sprouting roots
and growing anew
Reproduction through severing
bodily tissue
A gush of sticky white sap
seeking to seal the scar
Eventually both parent and child
recover

The detached child forming new roots
and growth, becoming a new plant...

Or are they still the same being?

Identical genetics in unique
circumstances.

Each taking their own form and
following an undetermined path.

Vine tendrils and feelers reaching out
and grabbing hold

A curved hook for latching, once
holding a wrapping curl secures the
connection

Rosemary leaves, so thin and small and yet
filled with incredible scent and flavor.

Dying away in the winter and
bursting forth in the spring. Each
year the roots expand
underground and emerging from
new ground. Climbing fences,
trees, and tomato cages.

Passion vine, *Passiflora*, fast growing with
purple flowers of extraordinary beauty
that last for a single day.
